CPSC 5031: Data Structures + Algorithms

HW # 4

### 1) Exercises 5.3 #1

```
public int LevelsDivideConquer(bt head) {  
    if (head == null) {  
        return 0;  
    }
```

```
    else {
```

```
        return Max(LevelsDivideConquer(bt head.left),  
                    LevelsDivideConquer(bt head.right)) + 1;  
    }
```

```
private int Max(int first, int second) {  
    if (first > second) {  
        return first;  
    }
```

```
    else {
```

```
        return second;  
    }
```

$T(n) = \Theta(n)$  because you have to traverse every node before determining which subtree path has the most levels.

\* 2) Exercise 5.3 #6

```
public void InOrderTraversal(bt head) {  
    if (head.left != null) {  
        InOrderTraversal(head.left);  
    }  
    Console.WriteLine(head.data);  
    if (head.right != null) {  
        InOrderTraversal(head.right);  
    }  
}
```

$T(n) =$

5-3-3

### 3) Section 5.3 - BST Traversal

- a. preorder (ELR):  
 + \* 4 3 - \* 2 1 5  
 b. inorder (LCR):  
 4 \* 3 + 2 \* 1 - 5  
 c. postorder (LRC):  
 4 3 \* 2 1 \* 5 - +

### 4) Section 6.4 - Heap construction

Bottom-up heap construction inserts new nodes at end and percolates up. Top-down heap construction inserts new nodes at the root and percolates down. Bottom-up is  $O(n)$  b/c in the percolate up, you have to compare the new node against every other node. Top-down is  $O(\log n)$  because you only have to traverse 1 of 2 subtrees in the percolate down portion.

### 5) Section 6.4 - Heapsort: Assuming Max Heap

[12 | 15 | 19 | 10 | 8 | 16 | 5] | [15 | 12 | 19 | 10 | 8 | 16 | 5] | [19 | 12 | 15 | 10 | 8 | 16 | 5]

[19 | 12 | 16 | 10 | 8 | 15 | 5]
